AI-Assisted Smart Library Recommendation System

Dummy One-Page Proposal | Proposal Extraction Demo 2

Title:

AI-Assisted Smart Library Recommendation System

Purpose:

To help university students discover relevant books, research papers, and digital resources according to their courses, interests, and current research topics.

Problem Statement:

Students often spend significant time searching for useful library resources. Existing searches usually depend on exact keywords and may not understand the student's research context or recommend related material.

Objectives:

1. Build a searchable digital library catalogue. 2. Recommend relevant resources using topic and keyword matching. 3. Save student search history and useful references. 4. Provide authorized resource access for students and supervisors.

Methodology:

The system will collect resource metadata, normalize titles and keywords, and rank results using deterministic relevance rules. A role-based web interface will allow students to search resources while administrators manage catalogue records and access permissions.

Expected Outcomes:

A faster and more organized academic resource discovery experience, improved research support for students, and a maintainable digital catalogue for university departments.

Keywords: smart library, academic search, resource recommendation, student research, digital catalogue
